

Lectures on comparative anatomy

This historic book may have numerous typos and missing text. Purchasers can download a free scanned copy of the original book (without typos) from the publisher. Not indexed. Not illustrated. 1834 Excerpt: ...molar teeth, and the adaptation, in the whole skeleton, for the horizontal posture of the trunk, which is common to most of the inferior orders of mammalia. The occipital foramen is still situated at the posterior margin of the cranium, and directed obliquely downwards and forwards. The mastoid cells are as large as those of a carnivorous quadruped, and although the orbit is surrounded by an osseous margin, it is continuous behind with the temporal fossa. The human sutures are here permanent, and correspond with the great development of the cranial cavity, and of the hemispheres of the brain. The sagittal suture continues onwards through the frontal bone, and the anterior frontals are as distinct as in the crocodiles, between the frontal, nasal, maxillary, and lachrymal bones. The temporal muscles are feeble, the skull is arched laterally, the temporal fossa small, the zygomatic arch feeble and almost horizontal, and the glenoid surface is flat, for the transverse flat condyle of the lower jaw. The lachrymal bones extend much from the orbits over the face, and are perforated on their facial portion. The nasal bones, unlike those of the higher quadrumana, are long, straight longitudinally, separate, broad, expanded above, and arched laterally throughout their course. The upper and lower maxillary bonea have a lengthened form to afford space for numerous teeth, and the condyle of the lower jaw is nearly as low as the alveoli of the teeth, from the shortness of the ramus. The angle of the lower jaw passes acutely backwards, and the coror compared with the long-muzzled lemurs and inferior animals we have been hitherto considering. Those organs of the senses,

lodged in the face, which we perceived comparatively so large in the inferior animals, are obviously begi...
