Effects of Heat.--Suppose we take a vessel filled with water. Let the vessel be a cylinder fitted with a piston, as shown in Fig. 142. The water is say at the freezing point, and the millions of molecules composing the water are moving to and fro with a comparatively small velocity. Place the vessel in a fire or furnace. Heat is communicated to the molecules of water, and they begin to move faster and faster and faster. That is, their kinetic energy increases, and, if a thermometer were inserted in the vessel, it would be found that the temperature of the water rises. Consequently, one effect of heat is to raise the temperature of the body to which it is applied. But, after reaching a certain temperature, the molecules of the water not only move faster, but they move further from each other and their paths are longer. It is plain that if the molecules are further apart than they were originally, the whole body of them must take up more space. In other words, after reaching a certain temperature, the water expands as heat is added. Hence, another effect of heat is to expand bodies to which it is applied. Common examples of the expansion of bodies by heat are seen in the setting of tires, the expansion of the rails of a railway in summer, etc. 659. The heat supplied to the vessel of water has so far done three things: 1. Raised the temperature of the water and thus increased the kinetic energy of the molecules. (Let the amount of heat expended for this purpose be denoted by S.) 2. A certain quantity of heat has been used in expanding the water; that is, in pushing its molecules further apart against

the force of cohesion. ...
